Richard C. Calderwood

“Express mail” label no. EU580770318US

NANOPOROUS DIAPHRAGM FOR ELECTROMAGNETIC TRANSDUCER

Background of the Invention

Technical Field of the Invention

This invention relates generally to electromagnetic transducers such as audio speakers, and more specifically to an improved diaphragm having a very low density, such as one formed from a nanoporous material such as aerogel.

Background Art

FIG. 1 illustrates a conventional audio speaker 10 such as is known in the prior art, shown as symmetrical about a center line CL. The speaker includes a motor structure 11 including a magnetic air gap. The motor structure is coupled to a diaphragm assembly 12 by a frame 13. The diaphragm assembly includes a diaphragm 14 which is coupled to the frame by a first suspension component 15 known as a surround. A bobbin or voice coil former 16 is coupled to the diaphragm. An electrically conductive voice coil 17 is coupled to the bobbin and is disposed within the magnetic air gap. The bobbin is coupled to the frame by a second suspension component 18 known as a spider. A dust cap 19 seals the diaphragm assembly and protects against infiltration of dust particles and other stray materials which might interfere with the operation or quality of the speaker.

The cone is typically very thin, on the order of 1mm thick. Conventional cones are made of paper, plastic, metal, or other such materials. It is desirable to minimize the mass of the diaphragm, to reduce the workload on the motor and improve the frequency response, efficiency, and acoustic accuracy of the speaker. It is also desirable to maximize the stiffness of the diaphragm, to avoid deformations under acceleration, which would produce acoustic distortion. These two goals are somewhat conflicting, in that the stiffness of the diaphragm can be increased by using thicker paper etc., which increases the diaphragm's mass.

Audax, a division of Harman International, offers a product line known as "High Definition Aerogel (HDA) cones". The HDA cones are only available in woofers and mid-bass woofers, and are only available as cone-shaped diaphragms for woofers and midrange speakers, not as domes for tweeters. Audax received U.S. Patent No. 5,380,960 on a process for

1 manufacturing the an aerogel material for speaker cones; this could possibly be the process by
2 which the HDA cones are manufactured. One exemplary Audax HDA speaker is the HM100Z2
3 “4-inch Aerogel cone mid/bass” driver. Its cone appears to be a conventional paper cone which
4 has had a shiny outer surface applied. The aerogel component, if any, might be this shiny skin;
5 or, it might be that aerogel has been intermixed with the paper fibers, either of which would
6 appear to be covered by the ‘960 patent. Regardless, the paper fibers comprise the vast majority
7 of the volume and the structural material of the “aerogel cone”, which has a thickness of only a
8 few thousandths of an inch, not discernibly different than any other conventional paper or plastic
9 cone. The overall density of the “aerogel cone” does not appear to be materially different than
10 that of a conventional paper cone. That being the case, in order to e.g. double the stiffness of the
11 Audax aerogel cone, it would be necessary to double the amount of the paper fiber or paper fiber
12 / aerogel mixture. This would double the mass of the cone.

13 FIG. 2 illustrates a speaker 20 having a solid or filled diaphragm 21, such as some models
14 of the KEF B139 which were available from KEF (England) in the 1960’s. The diaphragm is
15 either a solid block of polystyrene foam, or it is a polypropylene cone which has been filled with
16 a monolithic block of polystyrene foam. Polystyrene foam has a density of 0.01gm/cm^3 . Alloy
17 skinned polystyrene foam has an overall density of 0.027gm/cm^3 . Polystyrene foam is the
18 lightest material which has, to date, been used as a significant portion of a speaker diaphragm’s
19 volume or structural integrity.

20 FIG. 3 illustrates a speaker 30 having a diaphragm 31 whose volume has been increased –
21 or, put another way, whose density has been decreased – by the addition of a filler material into
22 the plastic of the cone. Filler materials which have been used include talc, carbon black, and
23 diatomaceous earth, typically as 10% of the total volume of the diaphragm material. This has
24 only a moderate impact on the density, because of the low percentage of filler material and the
25 relatively high density of the filler material itself.

26 FIG. 4 illustrates a conventional dome tweeter audio speaker 40. The tweeter includes a
27 dome diaphragm 41, which is traditionally formed from a thin sheet of fabric, metal, or plastic. A
28 surround 24 couples the dome assembly to the cup of the motor structure.

29 Due to their high operating frequencies, tweeters are commonly self-contained, meaning
30 that they enclose a volume 42 of captive air between the dome and the motor structure, which is

1 not vented. In order to reduce acoustic wave reflections from the hard top plate of the motor
2 structure, a quantity of acoustic damping material 43 is commonly affixed to the top plate, often
3 in a domed button shape somewhat smaller than the inside surface of the dome. The button needs
4 to be removed far enough from the dome, that the dome does not strike the button during
5 operation, lest the sound become distorted.

6 FIG. 5 illustrates an alternative embodiment of a tweeter dome 50 such as is sometimes
7 employed in the prior art. The dome consists of a very thin layer of flexible fabric. A center
8 portion of the fabric is formed into a dome 51, and a perimeter portion of the fabric is formed
9 into a surround 52 which is integral with the dome. The dome is commonly made rigid by adding
10 a stiffening material such as epoxy to its portion of the fabric, while the surround is not stiffened,
11 or is less stiffened than the dome. Similarly shaped domes are also formed of plastic. The thin
12 dome has a hollow, concave underside.

13 FIG. 6 illustrates a different tweeter dome 60 such as is sometimes employed in the prior
14 art. The dome has a laminated structure, including an exterior layer 61 and an interior layer 62,
15 and perhaps other, intermediate layers (not shown). The thin, laminated dome has a hollow,
16 concave underside.

17 FIG. 7 illustrates a conventional tweeter 40 exhibiting breakup modes of its dome 41
18 during operation of the tweeter. As the alternating current electrical signal causes acceleration of
19 the voice coil, such as in the extension (outbound) direction as illustrated, some portions of the
20 tweeter dome react more quickly to the acceleration than do other portions. In the example,
21 shown, the voice coil and bobbin are accelerating the dome upward, or extending the dome, and
22 the outer portions 71 of the dome are reacting in time with the bobbin, but the middle portion 72
23 of the dome is unable to react as quickly, and collapses inward. The central portion may actually
24 be moving outward, just at a slower rate than the outer portions of the dome, or, in extreme
25 cases, it may still be moving inward from the previous half cycle of operation. In more complex
26 cases, typically occurring at very high frequencies and high operating powers, the dome may
27 exhibit far more complex breakup modes, not limited to two portions as shown.

28 Much effort has been spent in the prior art, attempting to make tweeter domes more rigid,
29 to alleviate these breakup modes. These solutions, such as the laminated dome structure, do offer
30 some measure of increased rigidity of the diaphragm, but at the expense of significantly

1 increased mass of the diaphragm. The more massive the diaphragm (and other moving parts), the
2 less efficient the transducer will be, and the more power (magnetic and/or electrical) it will
3 require to effect an adequate acceleration of the diaphragm.

4 What is needed is an improved diaphragm which has a significantly decreased overall
5 density, such that its stiffness can be improved without increasing its mass, with respect to a
6 conventional diaphragm.

7 **Brief Description of the Drawings**

8 The invention will be understood more fully from the detailed description given below
9 and from the accompanying drawings of embodiments of the invention which, however, should
10 not be taken to limit the invention to the specific embodiments described, but are for explanation
11 and understanding only.

12 FIG. 1 shows, in cross-section, speaker having a conventional thin cone diaphragm
13 according to the prior art.

14 FIG. 2 shows, in cross-section, a speaker having a solid filled diaphragm according to the
15 prior art.

16 FIG. 3 shows, in cross-section, a speaker having a plastic-and-filler cone according to the
17 prior art.

18 FIG. 4 shows, in cross-section, a tweeter having a dome diaphragm according to the prior
19 art.

20 FIG. 5 shows, in cross-section, an integrally formed tweeter dome and surround,
21 according to the prior art.

22 FIG. 6 shows, in cross-section, a laminated tweeter dome, according to the prior art.

23 FIG. 7 shows, in cross-section, a prior art tweeter dome suffering breakup modes during
24 operation.

25 FIGS. 8-11 show, in cross-section, tweeters having domes according to several
26 embodiments of this invention.

27 FIGS. 12-18 show, in cross-section, details of different embodiments of tweeter domes
28 according to this invention.

1 FIG. 19 shows, in cross-section, a speaker having a filled cone according to another
2 embodiment of this invention.

3 FIG. 20 shows, in cross-section, a tweeter having a spherical dome according to one
4 embodiment of this invention.

5 FIG. 21 shows, in cross-section, a compression driver type electromagnetic transducer
6 having an inverted dome according to another embodiment of this invention.

7 FIG. 22 shows, in cross-section, a sandwiched cone embodiment of the invention.

8 Detailed Description

9 The invention may be utilized in a variety of magnetic transducer applications, including
10 but not limited to audio speakers, microphones, mechanical position sensors, actuators, and the
11 like. For the sake of convenience, the invention will be described with reference to audio speaker
12 embodiments, but this should be considered illustrative and not limiting.

13 FIG. 8 illustrates one embodiment of a tweeter 80 which utilizes a dome 82 according to
14 one embodiment of this invention. The dome is constructed of an ultra lightweight, solid,
15 nanoporous material, such as an aerogel, nanocomposites, or the like, hereinafter collectively
16 referred to as aerogel for convenience. The aerogel dome is coupled to a bobbin 84 which, in
17 some embodiments, may have a closed outer end 86 forming a plate or base to which the aerogel
18 dome is coupled such as with glue. A volume 88 of air is enclosed within the tweeter to provide
19 acoustic loading. The dome may in some embodiments be a hemisphere, as shown.

20 FIG. 9 illustrates another tweeter 90 utilizing a different embodiment of an aerogel dome
21 92. The bottom or underside of the dome is not flat, but is arched or concave to increase the
22 volume 94 of air enclosed within the tweeter. The inner or bottom surface and the outer or
23 exterior surface of the aerogel dome may be of similar concentric circle shapes, as shown. The
24 bobbin 96 does not have a closed outer end. In some embodiments, the bobbin may include a
25 truncated outer end which is partly closed to provide a platform 98 to which the dome is coupled.

26 FIG. 10 illustrates another tweeter 100 utilizing a slightly different embodiment of an
27 aerogel dome 102. The shape of the bottom surface of the dome does not necessarily have to be
28 the same as the shape of the outer surface. The skilled engineer will, given the demands of a
29 particular application and the teachings of this document, be able to make a suitable tradeoff

1 between the amount of aerogel to remove from the underside of the dome, which may tend to
2 reduce the overall structural stiffness of the dome, and the amount of air enclosed within the
3 tweeter.

4 FIG. 11 illustrates another tweeter 110 utilizing an aerogel dome 112 which is a less than
5 hemispherical section of a sphere. In some embodiments, the aerogel dome may not be a section
6 of a sphere, but rather a section of some other shape such as an elliptical object like a football, in
7 which case it will not have a circular footprint when viewed along the axis (that is, from the front
8 of the tweeter, or from the top of the page as illustrated). In some such cases, the dome may have
9 a hemispherical cross-section in one direction, and some other shape cross-section in another
10 direction or plane.

11 FIG. 12 illustrates one embodiment of a dome assembly 120 including a bobbin 122
12 which may advantageously be used with an aerogel dome 124. In order to improve mechanical
13 coupling of the dome to the bobbin, the bobbin may include one or more structures 126 which
14 penetrate inside the dome. Suitably, the dome may be manufactured e.g. by high temperature and
15 pressure-critical point drying of a gel composed of colloidal silica structural units filled with
16 solvents with the bobbin embedded inside the gel prior to drying. To further improve mechanical
17 coupling, the penetrating structures 126 may include lateral extensions 128 which increase the
18 surface area of bonding between the aerogel and the bobbin, and also provide direct mechanical
19 coupling.

20 FIG. 13 illustrates further details of an aerogel dome 130 which may be employed in
21 practicing this invention. In some cases, the naked aerogel structure 132 alone may not provide
22 sufficient surface strength, in some measure due to the exposed ends of its microfibrous
23 structures. In such cases, it is advantageous to provide the aerogel structure with an outer skin
24 134. In some embodiments, this outer skin may be formed by sputtering a suitable material onto
25 the surface of the aerogel. Alternative methods, such as chemical vapor deposition, laminating,
26 vacuum depositing, dipping, painting, or the like, may be used in some applications.

27 In some embodiments, the skin is formed of a material having high thermal conductivity,
28 to improve cooling of the tweeter.

29 In some embodiments, the skin is formed of an elastic material such as plastic, to enable
30 it to elastically damp any breakup modes that occur, however unlikely they may be, or to add

1 additional strength (e.g. to help recover from a finger poking the dome in, as is so often seen in
2 stereo shops).

3 The skin may be of any suitable thickness. In some embodiments, it may measure mere
4 angstroms thick, such as if gold is sputtered onto the surface of the aerogel. In others, it may be
5 significantly thicker. The thicker the skin, the greater strength it may offer, albeit at a mass
6 penalty. However, this will not often be a meaningful issue, as the rigidity of the aerogel enables
7 the skin to be minutely thick compared to the thin film or fabric domes of the prior art.

8 When faced with otherwise equally suitable choices of skin material, the designer may
9 optionally opt for the one which is aesthetically preferred, such as gold or the like.

10 The skin may be formed of any suitable material, which the skilled designer will select
11 according to the various demands of the application at hand, when armed with the teachings of
12 this disclosure. Metallic skin materials may include, but are not limited to, titanium, beryllium,
13 magnesium, scandium, aluminum, silver, gold, and alloys. Plastic skin materials may include,
14 but are not limited to, polycarbonate, polyester (PET), polyethylene naphthalate (PEN),
15 polyimide, and fluoropolymer. Skins other than metals or plastics can be used, as well, such as
16 various oxides of metals, of plastic, or of the aerogel itself.

17 In some embodiments, the skin may cover the entire aerogel dome structure, including its
18 outer surface and its bottom surface, as shown. In other embodiments, only a portion of the
19 aerogel structure is covered with the skin. In some such cases, it may be desirable to skin only
20 the bottom surface, to improve its strength and its resistance to damage by the bobbin. In other
21 such cases, it may be desirable to skin only the outer surface, to protect the aerogel from external
22 impacts.

23 In some embodiments, more than one skin material may be utilized. For example, a
24 laminated skin may be formed, by first painting a thin layer of plastic onto the aerogel, and then
25 sputtering a layer of titanium nitride onto the plastic. In other embodiments, the underside may
26 be skinned with a different material than the exterior surface. The skilled reader will appreciate a
27 wide variety of possibilities, when enlightened with the teachings of this disclosure.

28 FIG. 14 illustrates another embodiment of a tweeter dome assembly 140, in which the
29 skin 142 is formed not only over the aerogel structure 144, but over bobbin 146 as well. This
30 may offer some degree of improvement in the coupling of the dome to the bobbin. In some cases,

1 such as when the aerogel is formed with the bobbin in situ, it may be necessary or at least
2 simpler to skin the whole assembly, rather than try to mask off some parts. However, in other
3 embodiments, it may be desirable to skin only portions of the assembly.

4 FIG. 15 illustrates a similar embodiment of a tweeter dome assembly 150, with the
5 additional feature of the skin 152 being applied over the dome assembly after the voice coil 154
6 has been wound around the bobbin 156. This may improve mechanical coupling of the voice coil
7 to the bobbin, and may provide a smoother exterior surface of the bobbin / voice coil assembly to
8 reduce frictional issues with ferrofluid coolant bathing the voice coil assembly.

9 FIG. 16 illustrates another embodiment of a tweeter dome assembly 160 with a more
10 complex skin arrangement. The aerogel dome 161 is encapsulated in a first layer of skin 162.
11 That assembly is coupled to the bobbin 163, then the resulting assembly is encapsulated in a
12 second layer of skin 164. The voice coil 165 is wound around the resulting assembly, and then
13 the entire structure is encapsulated in a third layer of skin 166. The layers may be of the same
14 material, or of different materials, and may be applied in the same manner, or by different means.

15 FIG. 17 illustrates an aerogel dome 170 which is fabricated to include an integral bobbin
16 172 in a monolithic construction with the body 174 of the aerogel dome. The voice coil 176 is
17 wound directly onto the bobbin-like extension 172 of the aerogel dome.

18 FIG. 18 illustrates an aerogel dome assembly 180 which includes a “silo” shaped aerogel
19 dome having a hemispherical upper portion 182 and a cylindrical lower portion 184 for mating
20 with a bobbin 186. The bobbin extends below the bottom of the aerogel dome to support a voice
21 coil 188. The cylindrical sides of the lower portion of the aerogel dome fit inside and may be
22 glued to the bobbin.

23 FIG. 19 illustrates a speaker 190 having a diaphragm 191 which includes an external
24 shell 192 such as a polypropylene cone, which is filled with a solid filler body 193. The solid
25 filler body is formed of an aerogel or other such material, such that the overall density of the
26 diaphragm (the mass of the polypropylene cone plus the mass of the solid filler body, divided by
27 the volume of the polypropylene cone plus the volume of the solid filler body) is less than
28 0.025g/cm^3 or less than 0.01g/cm^3 . In some embodiments, the exterior surface of the solid filler
29 body may be protected by a skin (not shown) of any suitable material.

1 FIG. 20 illustrates another embodiment of a tweeter 200 utilizing a substantially spherical
2 aerogel dome 201. With other materials, this would be an unacceptably massive structure, which
3 the motor structure would be unable to adequately accelerate. However, due to the incredibly low
4 mass density of aerogel, aerogel diaphragms may be made of almost arbitrarily large sizes and
5 shapes. The spherical shape offers extremely high structural integrity.

6 A surround 202 may advantageously be coupled to the spherical aerogel dome at or near
7 the "equator" of the sphere. The bobbin 203 may be coupled to (or inserted into) the spherical
8 dome at any point, suitably a point dictated by the desired voice coil diameter of the motor
9 structure. A spider 204 may be coupled to the bobbin. A frame 205 may be coupled to the motor
10 structure to support the surround and the spider.

11 FIG. 21 illustrates a compression driver tweeter 210 which incorporates this invention.
12 The compression driver includes a body 211, 212 which forms a substantially sealed motor
13 chamber. The motor structure drives an inverted aerogel dome 213. The facing surfaces of the
14 aerogel dome and a phase plug 214 ideally have a substantially similar shape, or, in other words,
15 they have substantially mating dimensions. As the aerogel dome is driven toward the phase plug,
16 the volume of air in the space 215 between the dome and the phase plug is compressed, and
17 flows through channels 216 through the phase plug. Upon exiting the sealed motor chamber, the
18 compressed air waves pass out through a horn 217 which increases the volume or area of air that
19 is moved by the diaphragm, improving acoustic loading.

20 FIG. 3 may be understood to represent another embodiment of this invention, one not
21 contemplated by the prior art, one in which nanoporous particles have been used as fill material
22 intermixed with the e.g. polypropylene material of the cone. Even when mixed at the
23 conventional 10% volumetric ratio, the use of nanoporous material will provide a significant
24 density improvement over that of the talc etc. of the prior art. Additional improvements can be
25 achieved by using a greater percentage of nanoporous filler, such as 15%, 20%, 25%, 50%, 75%,
26 or more by volume. In some applications, the volume of the nanoporous particles may be less
27 than 1 cubic millimeter each, and there may be 1,000 or more such particles in each diaphragm.
28 In some applications, the nanoporous particles may be vastly smaller and their numbers vastly
29 greater, as per the needs of the application at hand.

1 One especially advantageous plastic which may be used in practicing this invention is
2 polymethylpentene, such as that available from Westlake Plastics Company, P.O. Box 127,
3 Lenni, PA 19052, under the trademark TPX®. TPX is a polyolefine which has the lowest
4 specific gravity (density) of any available thermoplastic, 0.833. TPX also has an excellent
5 strength to weight ratio, low water absorption, high melting temperature, and excellent acoustic
6 properties such as a low speed of sound propagation. Its has only recently come into use in a
7 very few audio speaker diaphragms, and in those it is used without filler material.

8 One especially useful characteristic of TPX is that it is translucent, and nearly
9 transparent, with only a slight amber tint. Aerogel is also nearly transparent. TPX filled with
10 aerogel particles offers all of the advantages of filled plastic diaphragms identified above, plus
11 the additional advantage that the filled plastic remains UV transparent, enabling the
12 manufacturer to use UV-cured adhesives to e.g. bond the diaphragm to the bobbin, bond the
13 spider to the bobbin, and so forth, from the readily-accessible front side of the speaker, curing
14 the adhesives right through the diaphragm.

15 Many purchasers appreciate the aesthetic appearance of a transparent diaphragm, which
16 makes the underlying spider, bobbin, voice coil, and other components visible. This aesthetic
17 appearance can be achieved either with the raw, nearly colorless TPX and aerogel, or in
18 combination with a color tint. In one embodiment, the color tint is added to the TPX. In another
19 embodiment, the color tint may be added to the aerogel particles. For example, some or all of the
20 aerogel particles, granules, or beads may be dyed. Alternatively, they may be coated with an
21 extremely thin layer of plastic or metal, such as by vapor deposition of an extremely thin layer of
22 gold, giving the diaphragm a transparent and yet shiny, metallic color. Alternatively, the metallic
23 particles could be added directly to the TPX.

24 FIG. 22 illustrates a diaphragm 220 according to another embodiment of this invention.
25 The diaphragm is a sandwiched cone (or other suitable shape) in which an upper layer 222 and a
26 lower layer 224 of polypropylene or other suitable material surround and encapsulate a volume
27 of nanoporous material 226. The nanoporous material may be a monolithic, rigid block or sheet,
28 or it may be comprised of a large number of small particles such as beads.

29 Conclusion

1 In the several embodiments shown above, various modifications, combinations, and
2 changes may be made within the scope of this invention.

3 In some embodiments, the diaphragm may have an internal mass density (of its aerogel
4 etc. filler, not counting its skin) in the range 0.0013-0.009g/cm³. In other embodiments, it may
5 have an internal mass density in the range 0.0013-0.005g/cm³. By way of contrast, polystyrene
6 foam has a density of approximately 0.01g/cm³.

7 In some embodiments, the diaphragm may have an overall mass density (including any
8 skin and any supporting cone) in the range 0.002-0.02g/cm³. In other embodiments, it may have
9 an overall mass density in the range 0.002-0.015g/cm³. By way of contrast, alloy skinned
10 polystyrene foam has a density of approximately 0.027g/cm³.

11 In some embodiments, nanoporous material makes up more than 50% of the overall
12 diaphragm by volume. In other embodiments, nanoporous material makes up more than 75% of
13 the overall diaphragm, by volume. In other embodiments, more than 90%. In other embodiments,
14 more than 95%. And in some other embodiments, more than 99% of the overall diaphragm is
15 nanoporous material, by volume.

16 When one component is said to be "adjacent" another component, it should not be
17 interpreted to mean that there is absolutely nothing between the two components, only that they
18 are in the order indicated. The various features illustrated in the figures may be combined in
19 many ways, and should not be interpreted as though limited to the specific embodiments in
20 which they were explained and shown. Reference in the specification to "an embodiment," "one
21 embodiment," "some embodiments," or "other embodiments" means that a particular feature,
22 structure, or characteristic described in connection with the embodiments is included in at least
23 some embodiments, but not necessarily all embodiments, of the invention. The various
24 appearances "an embodiment," "one embodiment," or "some embodiments" are not necessarily
25 all referring to the same embodiments. If the specification states a component, feature, structure,
26 or characteristic "may", "might", or "could" be included, that particular component, feature,
27 structure, or characteristic is not required to be included. If the specification or claim refers to "a"
28 or "an" element, that does not mean there is only one of the element. If the specification or
29 claims refer to "an additional" element, that does not preclude there being more than one of the
30 additional element. Those skilled in the art having the benefit of this disclosure will appreciate

1 that many other variations from the foregoing description and drawings may be made within the
2 scope of the present invention. Indeed, the invention is not limited to the details described above.
3 Rather, it is the following claims including any amendments thereto that define the scope of the
4 invention.
